(v2.1 released October 2007)

This work demonstrates that prostate tumour progression in vivo can be analysed by using solutions of a mathematical model supplemented by initial conditions chosen according to growth rates of cell lines in vitro. The mathematical model is investigated and solved numerically. Its numerical solutions are compared with experimental data from animal models. The numerical results confirm the experimental results with the growth rates in vivo.

Keywords: prostate tumour progression, growth rates of Pr-cell lines in vitro, animal models for prostate cancer, growth rates in vivo, mathematical model, numerical simulations.

AMS Subject Classification: 45K05, 34K28, 62P10

1. Introduction

The purpose of this paper is to analyse the C3(1)/Tag-Pr cell lines introduced in [1], [2], [3] and to develop a mathematical model which has a potential to describe the growth rates of Pr-cell lines in vivo. We have shown that the numerical solutions of the mathematical model can be used to predict the behaviour of the cancer cell populations in vivo.

Mathematical models of cancer growth have been the subject of research activity for many years. The models of [4–8] have used DNA content as a measure of the generic term 'cell size' to investigate the dynamics of the human cell cycle. For earlier studies on cell cycle dynamics, see [9–13]. Models which describe interactions between cancer cells and immune systems have been proposed e.g. in [14–16]. Another mathematical model for tumour growth has been recently studied in [17]. This model is formulated in radial coordinates and corresponds to brain cancer progression after surgical therapy. Different initial conditions explored in [17] correspond to a small remnant of tumour tissue left after surgical resection.

In this paper we have explored the model of [14] for the analysis of the C3(1)/Tag-Pr cell lines dynamics. The model is composed of five partial integro-differential equations. We supplement the model equations by different initial conditions which are chosen according to the experimental data described in [3].

different Pr-cell lines \textit{in vitro} from [3] are used as initial values for the model. Our goal is to solve the resulting initial-value problems and analyse their solutions, which show different progressions of tumours.

We construct numerical solutions for the initial-value problems and compare the computed approximations with the C3(1)/Tag cell lines \textit{in vivo}, which are described in [3]. The approximations show a good agreement between the experimental data of [3] and the data predicted by the model. They also show that the cancer progression is larger in the cases of larger initial values (larger number of cancer cells injected) than in the cases of smaller initial values imposed as the initial conditions in the model. This confirms the correlation (illustrated in [3]) between the \textit{in vitro} growth characteristics of the cell lines and the \textit{in vivo} growth of tumours.

The organization of the paper is the following. Section 2 describes \textit{in vitro} cell growth in flasks and \textit{in vivo} cell growth in C3(1)/Tag Mice. Then the mathematical model of the cancer growth is described in Section 3. Numerical approximations to the solutions of the model are constructed in Section 4. Results of our numerical experiments are presented and compared with experimental data in Section 5. Concluding remarks and future goals are described in Section 6.

2. \textit{In vitro} cell growth in flasks and \textit{in vivo} cell growth in C3(1)/Tag Mice

Over 220 000 men in the USA are diagnosed with prostate cancer every year [18]. Of these, 26 000 will succumb to the disease as a result of widespread metastasis to secondary organs, primarily the bones, lungs and liver [19]. These statistics suggest the need for improved early detection techniques and treatment options.

Prostate cancer progression is characterized by distinct morphological characteristics signifying various stages. PIN, prostatic intraepithelial neoplasia, is believed to be the precursor lesion to prostate adenocarcinoma [20]. Inevitably, invasive adenocarcinoma will enter into systemic circulation and potentially develop secondary tumours as metastases. These highly aggressive, metastatic cells are the source of many complications associated with cancer in addition to the ultimate cause of death [21]. Good model systems are needed that allow for an increased understanding of the molecular alterations occurring during human prostate tumour progression.

The C3(1)/Tag transgenic mouse model of prostate cancer was developed by expressing the transforming sequences of the SV40 large T antigen (SV40 Tag) in tissues utilizing the regulatory sequences of the rat steroid binding protein C3(1) ([22], [23]). Prostates of transgenic mice develop low and high grade PIN from 2 – 7 months of age and adenocarcinoma after 6 months [24]. Based upon the predictable progression of tumour development in this model, a series of cell lines from C3(1)/Tag mice at different cancer stages were established, including the low-grade PIN cell line, Pr111 [1] and the high-grade PIN cell line, Pr117 [3]. Pr14 was established in tissue culture from a 6 month old C3(1)/Tag mouse prostate and is an aggressive adenocarcinoma cell line [2]. Nude mouse studies involving the subcutaneous injection of Pr14 cells resulted in a rare lung metastasis. These lesions were isolated and established in culture as novel metastatic cell lines, Pr14C1 and Pr14C2 [3].

In both \textit{in vitro} and \textit{in vivo} analyses, the five cell lines could be distinguished by their growth characteristics. Using an \textit{in vitro} proliferation assay, early passage (5-10) cells were cultured on collagen-coated flasks (Corning, NY) in mammary epithelial growth media (MEGM) (Bio-Whittaker, Walkersville, MD) supplemented with 2% fetal bovine serum (Invitrogen, Carlsbad, CA) and 4 nM of the synthetic androgen mibolerone (Sigma, St. Louis, MO) [3]. $10^4$ cells/well were grown for 5 days in 6-well plates, trypsinized, and counted daily using a Neubauer hemacytometer chamber (Hausser Scientific, Horsham, PA). The low-grade PIN cell line Pr111 had the lowest proliferation rate, Pr117, Pr14, and Pr14C2 had intermediate growth rates, and the metastatic Pr14C1 had the fastest rate of proliferation [3] (see Fig. 1).

The \textit{in vivo} growth rate of the cell lines correlated well with the \textit{in vitro} results. $10^6$ cells/0.2ml saline were subcutaneously injected into 5 – 6 month old syngeneic C3(1)/Tag male mice [3]. Only three of five mice injected with Pr111 cells developed small tumours ($< 200 \text{ mm}^3$) 10 – 11 weeks after injection.
Injection of all of the other cell lines produced large tumors that grew rapidly in five of five mice between 2 and 6 weeks after injection. Pr14C1 cells were the most aggressive \[3\]. These cell lines establish a model system with a cell line of low tumorigenicity (Pr111), cell lines with intermediate tumorigenicity (Pr117, Pr14, Pr14C2), and a cell line with high tumorigenicity (Pr14C1).

3. Mathematical model

We follow the idea of \[14\] and investigate the development of cancer cells by means of mathematical equations. As in \[14\] we denote by

\[ f_i(t, u), \quad f_i : [0, \infty) \times [0, 1] \rightarrow R_+, \quad i = 1, \ldots, 6, \]
the distribution density of the $i$-th population with activation state $u \in [0,1]$ at time $t \geq 0$. Moreover, let

$$n_i(t) = \int_0^1 f_i(t, u) du, \quad n_i : [0, \infty) \rightarrow \mathbb{R}^+, \quad i = 1, \ldots, 6,$$

be the concentration of the $i$-th cells at time $t \geq 0$. Here, the subscript $i = 1$ refers to the cancer cells (CCs). The other five populations described in our model are the helper T cells (Th), denoted by the subscript $i = 2$, the cytotoxic T lymphocytes (CTLs), denoted by the subscript $i = 3$, the antigen presenting cells (APCs), denoted by the subscript $i = 4$, the antigen-loaded APCs ($[\text{Ag-APC}]$), denoted by the subscript $i = 5$, and the cells of the host environment (HE), denoted by the subscript $i = 6$.

Here, the activation state of a given CC denotes the probability of recognition of this CC by APCs. The higher the probability, the higher is the possibility of the immune system to perform effective destruction of the tumour cell. On the contrary, if the activation state of a CC is small ($u \approx 0$) then the CC is "invisible" for the APCs, e.g. due to antigenic modulation [25] (the disappearance of detectable tumour-specific antigens from the surface of the CC). Therefore, the smaller the activation state of a CC, the more dangerous is the tumour cell.

In our model, the activation state of a given CTL is defined as the probability of the destruction of a recognized CC after the interaction with the given CTL. The population of Th cells is involved in the activation and the proliferation of immune cells (e.g. APCs, CTLs, Th cells, B cells) by the production and the secretion of cytokines leading to the generation and the activation of immune cells [26]. In our model, the activation state of a given Th cell is defined as the quantity of cytokines produced by the Th cell after its interaction with antigen-loaded APC, normalized with respect to the maximal possible production of cytokines.

As a simplification of the biological reality we admit the following assumptions. For the populations denoted by $i = 4, 5$ and 6, we neglect the possible change of their activity and assume that only some fixed state of activation (say $u = 0.5$) is possible. The distribution function $f_i$ of the HE is assumed to be constant in time. We take into account only binary cell interactions which are supposed to be homogeneous in space and without time delay. These encounters may change the activation state of cells as well as create or destroy cells.

Our model describes the cellular immune response against cancer [25]. The following interactions are taken into account. We assume that the interactions between CCs and HE lead to the production of new CCs as well as to decreasing the possibility of the immune system to recognize the CCs (thus they become more dangerous). The production of new cancer cells is assumed to be proportional to the number of existent CCs. The respective gain term is

$$p^{(1)}_{16} \int_0^1 f_1(t, v) dv.$$

The activation state of CCs decreases and this change of activity is described by the term

$$t^{(1)}_{16} \left(2u \int_u^1 f_1(t, v) dv - u^2 f_1(t, u)\right).$$

Specific Th1 cells and CTLs are involved in the elimination of cancer cells. We assume that the number of destroyed CCs is proportional to the activation states of Th cells and CTLs and the respective loss
terms are
\[ d_{1i} f_1(t, u) \int_0^1 v f_i(t, v) \, dv, \quad i = 2, 3, \quad u \in [0, 1], \]

see [14] for more details. Thus we obtain the equation
\[ \frac{\partial f_i}{\partial t}(t, u) = p_{16}^{(i)} \int_0^1 f_1(t, v)dv + t_{16}^{(i)} \left( 2u \int_0^1 f_1(t, v)dv - u^2 f_1(t, u) \right) \]
\[ - d_{12} f_1(t, u) \int_0^1 v f_2(t, v)dv - d_{13} f_1(t, u) \int_0^1 v f_3(t, v)dv \]
(2)

for the time evolution of the CCs.

In our model, the time evolution of the populations \( i = 2 \) and \( 3 \) depends on the following factors: the constant production of T cells (Th cells and CTLs) by HE, the generation of T cells as well as the increasing of the activation states of Th cells and CTLs due to the interactions between Th cells and antigen-loaded APCs, the destruction of T cells resulting from their interactions with cancer cells, the natural death of T cells and the possible inlet of T cells.

There are observations that the HE constantly produces T cells and APCs [26]. The activity of newly generated T cells is small and it increases during their development and selection [25]. We model the process of the production of Th cells and CTLs by the gain terms
\[ p_{16}^{(i)} (1 - u), \quad i = 2, 3. \]

The interactions between Th cells and antigen-loaded APCs induce a generation of new Th cells and CTLs. We assume that the rate of this production is proportional to the activation states of Th cells and that the probability of creation of very active T cells is less than the probability of the creation of less active T cells. The respective gain terms are
\[ p_{25}^{(i)} (1 - u) n_5(t) \int_0^1 v f_2(t, v)dv, \quad u \in [0, 1], \quad i = 2, 3. \]

The interactions between Th cells and antigen-loaded APCs lead to an increase in the activation states of Th cells and CTLs. We assume that the change of the activity of Th cells depends on the number of antigen-loaded APCs and is described by the term
\[ t_{25}^{(2)} n_5(t) \left( 2 \int_0^u (u - v) f_2(t, v)dv - (1 - u)^2 f_2(t, u) \right). \]

We assume that the change of the activity of CTLs depends on the number of Th cells and is described by the term
\[ t_{23}^{(3)} \left( 2 \int_0^u (u - v) f_3(t, v)dv - (1 - u)^2 f_3(t, u) \right) \int_0^1 f_2(t, v)dv. \]

The interactions between T cells and CCs may result in apoptosis of Th cells and CTLs [26]. We assume
that the respective loss terms for the populations $i = 2$ and $3$ are

$$d_i f_i(t, u) \int_0^1 f_1(t, v) \, dv, \quad i = 2, 3.$$  

The natural death of Th cells and CTLs is described by the terms

$$d_i f_i(t, u), \quad i = 2, 3,$$

and the possible influx of Th cells and CTLs is described by

$$S_i(t, u), \quad i = 2, 3.$$

In this way, we obtain

$$\frac{\partial f_2}{\partial t}(t, u) = p_{16}^{(2)} (1 - u) + p_{25}^{(2)} (1 - u)n_5(t) \int_0^1 vf_2(t, v) \, dv - d_21 f_2(t, u) \int_0^1 f_1(t, v) \, dv$$

$$-d_26 f_2(t, u) + t_{25}^{(2)} n_5(t) \left( 2 \int_0^u (u-v)f_2(t, v) \, dv -(1-u)f_2(t, u) \right) + S_2(t, u) \quad (3)$$

and

$$\frac{\partial f_3}{\partial t}(t, u) = p_{16}^{(3)} (1 - u) + p_{25}^{(3)} (1 - u)n_5(t) \int_0^1 vf_2(t, v) \, dv - d_31 f_3(t, u) \int_0^1 f_1(t, v) \, dv$$

$$+t_{23}^{(3)} \left( 2 \int_0^u (u-v)f_3(t, v) \, dv -(1-u)f_2(t, u) \right) \int_0^1 f_2(t, v) \, dv - d_36 f_3(t, u) + S_3(t, u) \quad (4)$$

for the time evolution of the populations $i = 2$ and $3$, respectively.

For the time evolution of the 4-th population of APCs, we assume their constant production by HE described by the term $p_{16}^{(4)}$ as well as production of APCs due to the interactions between Th cells and antigen-loaded APCs with a rate proportional to the state of activity of Th cells described by the term

$$p_{25}^{(4)} n_5(t) \int_0^1 vf_2(t, v) \, dv.$$

A part of APCs is loaded with cancer antigens due to the interactions between APCs and CCs [25]. We assume that the concentration of new antigen-loaded APCs is proportional to the state of activity of CCs and is described by the term

$$b_{14}^{(5)} n_4(t) \int_0^1 vf_1(t, v) \, dv.$$

We note that this term is a loss term for the fourth population of APCs and it is a gain term for the fifth population of [Ag-APCs]. Taking into account also the natural death process of APCs described by the term

$$d_46 n_4(t),$$
we obtain the equation
\[
\frac{d}{dt} n_4(t) = p_1^{(4)} + p_2^{(4)} n_5(t) \int_0^1 v f_2(t, v) dv - b_1^{(5)} n_4(t) \int_0^1 v f_1(t, v) dv - d_{46} n_4(t)
\]  
(5)
for the time evolution of the population \( i = 4 \).

We also consider the possible source term \( S_5(t) \) of antigen-loaded APCs, the natural death of [Ag-APCs] described by the term
\[
d_{56} n_5(t)
\]
as well as their destruction by cancer cells described by the term
\[
d_{51} n_5(t) \int_0^1 f_1(t, v) dv.
\]

This leads to the equation
\[
\frac{d}{dt} n_5(t) = b_1^{(5)} n_4(t) \int_0^1 v f_1(t, v) dv - d_{51} n_5(t) \int_0^1 f_1(t, v) dv - d_{56} n_5(t) + S_5(t)
\]  
(6)
for the time evolution of the population \( i = 5 \).

The entire model (2)-(6) for the interacting populations is a system of partial integro-differential equations. Note that (2)-(6) is not complete and has to be supplemented by initial conditions. We apply the experimental data of [3] for the initial conditions and choose different Pr-cell lines \textit{in vitro} as initial values. The values of the parameters of the model can be found by using experimental data and numerical approximations to the solutions of (2)-(6). The approximations are constructed in Section 4.

4. Approximate solution of the model

The purpose of this section is to construct a numerical solution to the concentrations of cells \( n_i(t) \), \( i = 1, \ldots, 5 \), at any time variable \( t > 0 \). The concentrations \( n_1(t) \), \( n_2(t) \), and \( n_3(t) \) can be computed from (1) by using the functions \( f_1(t, u) \), \( f_2(t, u) \), and \( f_3(t, u) \). To compute numerical approximations to the values \( f_1(t, u) \), \( f_2(t, u) \), \( f_3(t, u) \), \( n_4(t) \), and \( n_5(t) \), we discretize the system (2)-(6) with respect to the activation state \( u \in [0, 1] \) by applying the uniform grid-points
\[
u_i = i \Delta u, \quad i = 0, \ldots, N,
\]
where \( N \) is a positive integer and \( \Delta u = 1/N \). Then the values \( f_1(t, u) \), \( f_2(t, u) \), and \( f_3(t, u) \) in (2)-(6) can be replaced by their approximations
\[
f_j(t, u_i) \approx f_{j,i}(t), \quad j = 1, 2, 3,
\]  
(7)
at the state grid-points \( u_i \in [0, 1] \). Similarly, the values \( S_2(t, u) \) and \( S_3(t, u) \) can be replaced by the approximations
\[
S_j(t, u_i) \approx S_{j,i}(t), \quad j = 2, 3.
\]  
(8)
For every \( t > 0 \) and every \( u_i \in [0, 1] \) with \( i = 0, \ldots, N \), we apply the approximations (7) for quadrature formulas to approximate the integrals:

\[
\begin{align*}
\int_0^1 f_j(t,v) dv & \approx Q_0^N \left[ f_j(t,v) \right], \quad j = 1, 2, \\
\int_0^1 v f_j(t,v) dv & \approx Q_0^N \left[ v f_j(t,v) \right], \quad j = 1, 2, 3, \\
\int_0^1 f_1(t,v) dv & \approx Q_1^N \left[ f_1(t,v) \right], \\
\int_0^1 (u_i - v) f_j(t,v) dv & \approx Q_0^N \left[ (u_i - v) f_j(t,v) \right], \quad j = 2, 3.
\end{align*}
\]

The approximations in (9) represent arbitrary quadratures. For example, in Section 5, the values \( Q_0^N \left[ f_j(t,v) \right], Q_0^N \left[ v f_j(t,v) \right], Q_1^N \left[ f_1(t,v) \right] \), and \( Q_0^N \left[ (u_i - v) f_j(t,v) \right] \) are computed by the composite trapezoidal rule.

The approximations (7), (8), and (9) applied to the partial integro-differential system (2)-(6) result in the following system of ordinary differential equations:

\[
\begin{align*}
\frac{df_1}{dt}(t) & = p_{16}^{(1)} Q_0^N \left[ f_1(t,v) \right] + t_{16}^{(1)} \left( 2u_i Q_i^N \left[ f_1(t,v) \right] - u_i^2 f_{1,i}(t) \right) - d_{12} f_{1,i}(t) Q_0^N \left[ v f_2(t,v) \right] \\
& \quad - d_{13} f_{1,i}(t) Q_0^N \left[ v f_3(t,v) \right] \\
\frac{df_2}{dt}(t) & = p_{16}^{(2)} (1 - u_i) + p_{25}^{(2)} (1 - u_i) n_5(t) Q_0^N \left[ v f_2(t,v) \right] - d_{21} f_{2,i}(t) Q_0^N \left[ f_1(t,v) \right] - d_{26} f_{2,i}(t) \\
& \quad + t_{25}^{(2)} n_5(t) \left( 2Q_0^N \left[ (u_i - v) f_2(t,v) \right] - (1 - u_i)^2 f_{2,i}(t) \right) + S_{2,i}(t) \\
\frac{df_3}{dt}(t) & = p_{16}^{(3)} (1 - u_i) + p_{25}^{(3)} (1 - u_i) n_5(t) Q_0^N \left[ v f_2(t,v) \right] - d_{31} f_{3,i}(t) Q_0^N \left[ f_1(t,v) \right] \\
& \quad + t_{23}^{(3)} \left( 2Q_0^N \left[ (u_i - v) f_3(t,v) \right] - (1 - u_i)^2 f_{3,i}(t) \right) Q_0^N \left[ f_2(t,v) \right] - d_{36} f_{3,i}(t) + S_{3,i}(t) \\
\frac{dn_1}{dt}(t) & = p_{16}^{(4)} + p_{25}^{(4)} n_5(t) Q_0^N \left[ v f_2(t,v) \right] - b_{14}^{(5)} n_4(t) Q_0^N \left[ v f_1(t,v) \right] - d_{46} n_4(t) \\
\frac{dn_3}{dt}(t) & = b_{14}^{(5)} n_4(t) Q_0^N \left[ v f_1(t,v) \right] - d_{51} n_5(t) Q_0^N \left[ f_1(t,v) \right] - d_{56} n_5(t) + S_5(t)
\end{align*}
\]

The equations in (10) are solved in Section 5. The numerical solutions \( f_{j,i}(t) \), with \( j = 1, 2, 3 \) and \( i = 0, \ldots, N \), are then used to compute the approximations to the functions \( n_1(t) \), \( n_2(t) \), and \( n_3(t) \). The approximations are computed from

\[
n_j(t) \approx Q_0^N \left[ f_j(t,v) \right], \quad j = 1, 2, 3.
\]

5. Numerical experiments

The purpose of this section is to solve system (10) and compare its solutions with the C3(1)/Tag cell lines and their growth characteristics \textit{in vivo} presented in [3], Fig. 1I (see Fig. 1). System (10) is not complete and needs to be supplemented by initial conditions. We apply the C3(1)/Tag cell lines \textit{in vitro} presented in [3], Fig. 1H (see Fig. 1) as the initial values for (10).

The composite trapezoidal rule is applied to the approximations (9) and (11). The equations in (10) are
solved by the code `ode15s` from the Matlab ODE suite [27]. The numerical solutions of (10) are computed with `AbsTol = 10^{-6}` and `RelTol = 10^{-2}`. The approximations to \( f_{1,i}(t) \), with \( i = 0, \ldots, N \), are then applied to (11).

The computed approximations to \( n_1(t) \) are presented in Fig. 2(b). For comparison, the experimental data from [3, Fig. 1I] are given in Fig. 2(a). The experimental and numerical data illustrate the \( C3(1)/Tag \) cell lines and their growth characteristics \textit{in vivo}.

(a) Experimental data  
(b) Predicted data

![Figure 2. Experimental versus predicted data.](image)

Fig. 2 indicates that the model describes accurate growth characteristics of the Pr-cell lines \textit{in vivo}. The numerical solutions presented in Fig. 2(b) illustrate the \textit{in vivo} tumour growth rates of the cell lines \textit{Pr}111, \textit{Pr}117, \textit{Pr}14, \textit{Pr}14C2, and \textit{Pr}14C1. The \textit{Pr}111 cells show low tumourigenicity, while the \textit{Pr}117, \textit{Pr}14, and \textit{Pr}14C2 cells show intermediate tumourigenicity, and the \textit{Pr}14C1 show high tumourigenicity.

The numerical solution for the growth rate of the cell line \textit{Pr}111 is computed from the model (10) supplemented by the smallest initial value (the smallest \textit{in vitro} rate of proliferation) indicated in [3, Fig. 1H] (see Fig. 1). Therefore, the rate of growth indicated in Fig. 2(b) for \textit{Pr}111 is the smallest (the solid line close to the time axis). On the other hand, the numerical solution for the growth rate of the cell line \textit{Pr}14C1 is computed from (10) with the largest initial value (the largest \textit{in vitro} rate of proliferation) indicated in [3, Fig. 1H] and the rate of growth shown in Fig. 2(b) for \textit{Pr}14C1 is the largest.

The numerical solutions for the growth rates of \textit{Pr}117, \textit{Pr}14, and \textit{Pr}14C2 are presented in Fig. 2(b) by the dotted, dash-dotted, and dashes lines, respectively. These numerical solutions are computed from the model (10) supplemented by the initial values chosen from [3, Fig. 1H] for \textit{Pr}117, \textit{Pr}14, and \textit{Pr}14C2, respectively. These initial values are intermediate between the initial values for \textit{Pr}111 and \textit{Pr}14C1 and the corresponding numerical solutions for \textit{Pr}117, \textit{Pr}14, and \textit{Pr}14C2 are intermediate between the numerical solutions of \textit{Pr}111 and \textit{Pr}14C1.

The numerical results presented in Fig. 2(b) confirm the experimental results of [3] and show that the \textit{in vitro} growth characteristics of cell lines correlate well with the \textit{in vivo} growth of tumours.

6. Concluding remarks

We have presented a correlation between numerical and experimental results. The numerical results have been obtained by solving a system of partial integro-differential equations. Growth rates of prostate cancer cell lines \textit{in vitro} have been used as initial values for the initial conditions supplementing the model equations. The numerical approximations to the solutions of the resulting model have shown a good agreement with \textit{in vivo} growth of tumours. Different kinds of tumourigenic cell lines have been illustrated by
the numerical solutions of the mathematical model. The numerical results have confirmed the experimental results by showing that growth rates in vivo correlate with growth rates in vitro.

Our future work will address an efficient algorithm for finding precise parameter values for the model equations. For this algorithm, we will adopt our method presented in this paper. The method will be used to compute numerical solutions for the model with different parameter values. The numerical solutions will then be compared with the experimental data to compute their errors. In order to obtain the model outputs as close as possible to the experimental data, we will minimize the sum of the squared errors.
