Waveguide-Fed Lens Based Beam-Steering Antenna
For 5G Wireless Communications

Abstract— In this paper, a two-dimensional cylindrical Lens antenna based on the parallel plate technique is designed. It supports beam-steering capability of 58° at 28 GHz. The antenna is composed of low loss rectangular waveguide antennas, which are positioned around a homogeneous cylindrical Teflon lens in the air region of two conducting parallel plates. The Beam scanning can be achieved by switching between the antenna elements. The main advantages of our design include its relative simplicity, ease of fabrication, and high-power handling capability. Compared to previous works including a curvature optimization for the plate separation of the parallel plates, the proposed antenna has a constant distance between plates. At the 28 GHz, the maximum simulated gain value is about 19 dB. Furthermore, the designed antenna only deviates about 0.4 dB over the 58° scan range.

Index Terms— Rectangular waveguide, Luneburg lens, mm-wave, beamsteering, fan beam.

I. INTRODUCTION

Millimeter-wave antenna design is considered as the first step for realizing mm-wave wireless communication systems. Design requirements for such antennas include highly directional patterns. Based on this demand, Luneburg lens (LL) antenna is an attractive choice at next generation wireless communications (5G) systems to create high gain directional radiation patterns [1], [2]. Recently, several works of two-dimensional parallel plates waveguide (PPW) designs with fan beam scanning capability have been a subject of extensive research [4], [5]. In this letter, a simple structure of PPW inspired multibeam antenna is demonstrated. In contrast to previous works used planar microstrip feeds, we are using metallic waveguides which have low loss, compact and slim features to fit between plates. Furthermore, the two parallel plates are separated by a constant distance. However, in previous PPW antennas the distance between the two parallel plates varies along with the plates length, forming a non-linear curvature.

II. DESIGN AND CONFIGURATION

Fig. 1 shows the three-dimensional view of the proposed beamsteering antenna. It mainly consists of three parts: feeding-network, the dielectric lens and conductive two parallel plates. The proposed lens with relative dielectric constant of $\varepsilon_r = 2.1$ and $\tan\delta = 0.0002$ has cylindrical cross section sandwiched between the plates. To estimate lens parameters, from antenna theory [4], the E-plane half-power beamwidths of the LL is given by the expression:

$$BW_E \approx 29.4\left(\frac{\lambda_0}{R_0}\right)$$  \hspace{1cm} (1)

Fig. 2: The simulated radiation pattern at 28 GHz of the feeding element.

this approximation, for achieving maximum gain and less sidelobe level the aperture of the RW was swept in a distance from the lens surface to determine the optimal feed position. Ultimately, the optimal position is achieved at 0.32Ro distance from the edge of the lens. The E-palne and H-plane radiation patterns of the feeding element integrated with parallel plate and lens is shown in Fig. 2. At the Plate spacing of 0.54λ0, the simulated 3-dB beamwidth in E-plane and H-plane is about 6.4° and 40° degree respectively. Since the cylindrical lens has a continuous focal arc around its circumference, multiple feed elements placed next to each other with a angular spacing of 7.2 degree. Fig. 3 depicts the simulated reflection coefficient of the multiple RW feeds versus frequency (GHz). It can be seen that the simulated reflection coefficient is less than -18.0 dB at 28 GHz for all ports. Due to symmetry around the center port, symmetrical ports are shown with the same color. Ideally, signals of two adjacent ports will interfere with each other. By exciting each port, a distinct beam is created in the desired direction. The radiation pattern of the resulting beam-steering for all feeds is shown in Fig. 4. Table I demonstrates the radiation characteristics achieved by each excited port. As displayed, multiple beams within a range of 58° with a gain variation of less than 0.4 dB resulted in a 3-dB beamwidth of about 6.15° – 6.42°.

IV. CONCLUSION

A simple and low loss design of PPW lens based antenna with beam steering capability has been designed at 28 GHz. The antenna is fed with an array of metallic rectangular waveguides to overcome the transmission losses of conventional PPW antennas at high frequencies. The simulated results show a good impedance bandwidth and good radiation patterns at the operation frequency.
